Vibrational Emission of Multiple Types of Trains from Source to Receiver Taha Alyousef 2017 In-motion trains' vehicles generate high intensity vibrations. The manner in which vibrations impact buildings' structures varies upon many factors that were discussed in this research. In this study, an analytical comparison of the difference in vibration emission between two types of trains (passenger train and cargo trains) concerning ground-borne vibration was conducted and two types of wave barriers (Open trench and in-filled trench) near buildings were analyzed. Solutions were discussed at the source, at the path and at the receiver. Yet, a particular emphasis was made at the receiver. Moreover, vibrations emission from trains, transmission in the ground and admittance into buildings were considered meticulously. The field measurement was conducted in Lucas County, Ohio, next to a train track where passenger and cargo trains operated on the same track. A private property was chosen near the train where the field measurement took place. Three 3-D accelerometers were placed at four different distances to measure the

incoming vibrations. The process of collecting data lasted about two weeks. Over 40 train measurements were recorded for analysis. Low and high frequency waves are tackled differently when it come to vibration attenuation and damping techniques to protect potential structures. This research has elaborated on the difference in wave emission of different trains by predicting such vibrations at the source and mitigating the by-product effects of vibrations at the receiver. The other part of this study is concerning ground vibration countermeasures, i.e., wave barriers (open and in-filled trenches) around buildings. The wave barrier method is achieved by excavating a trench between the source of vibration and the potential affected structure. One aim of this study was to identify which mitigation practice served the potential affected building best, under the influence of low and high frequency waves, with reference to efficacy and practicality. Vibration interaction occurrence at track-ground-building has been examined by researchers. Nonetheless, no emphasis has been found on how different trains and the variance in wave frequencies affect nearby buildings. Therefore, the intension of this study is to fulfill that gap by elucidating such an occurrence.

Foundation Vibration Analysis Using Simple Physical Models John P. Wolf 1994 This book provides simple physical models to represent the unbounded soil in time and frequency domain analysis. They do not supplant the more generally applicable rigorous methods, but rather supplement them. The physical models used consists of the following representations: cones based one-dimensional rod theory; lumped-parameter models with frequency-independent springs, dashpots, and masses; and prescribed wave patterns in the horizontal plane. The physical models thus offer a strength-of-materials approach to foundation dynamics.

Vibrations of Elasto-Plastic Bodies Vladimir Palmov 1998-04-08 Undeservedly little attention is paid in the vast literature on the theories of vibration and plasticity to the problem of steady-state vibrations in elastoplastic bodies. This problem, however, is of considerable interest and has many important applications. The problem of low-cyclic fatigue of metals, which is now in a well developed state is one such application. The investigations within this area are actually directed to collecting experimental facts about repeated cyclic loadings, cf. [47]. Theoretical investigations within this area usually consider the hysteretic loops and the construction of models of plasticity theory which are applicable to the analysis of repeated loadings and the study of the simplest dynamic problems. Another area of application of the theory of the vibration of elastoplastic bodies is the applied theory of amplitude-dependent internal damping. Another name for this theory is the theory of energy dissipation in vibrating bodies. In accordance with the point of view of Davidenkov "internal damping" in many metals, alloys and structural materials under considerable stress presents exactly the effect of micro plastic deformations. Therefore, it may be described by the methods of plasticity theory. This point of view is no doubt fruitful for the theory of energy dissipation in vibrating bodies, as it allows one to write down the constitutive equations appropriate both for vibrational analysis of three-dimensional stress states and an investigation of nonharmonic deformation. These problems are known to be important for the theory of internal damping.

Vehicle Gearbox Noise and Vibration Jiri Tuma 2014-02-20 Advances in methods of gear design and the possibility of predicting the sound pressure level and life time of gearboxes and perfect instrumentation of test stands allows for the production of a new generation of quiet transmission units. Current literature on gearbox noise and vibration is usually focused on a particular problem such as gearbox design without a detailed description of measurement methods for noise and vibration testing. **Vehicle Gearbox Noise and Vibration: Measurement, Signal Analysis, Signal Processing and Noise Reduction** Measures addresses this need and comprehensively covers the sources of noise and vibration in gearboxes and describes various methods of signal processing. It also covers gearing design, precision manufacturing, measuring the gear train transmission error, noise test on testing stands and also during vehicle pass-by tests. The analysis tools for gearbox inspection are based on the frequency and time domain methods, including envelope and average tooth mesh analysis. To keep the radiated noise under control, the effect of load, the gear contact ratio and the tooth surface modification on noise and vibration are illustrated by measurement examples giving an idea how to reduce transmission noise. Key features: Covers methods of processing noise and vibration signals Takes a practical approach to the subject and includes a case study covering how to successfully reduce transmission noise Describes the procedure for the measurement and calculation of the angular vibrations of gears during rotation Considers various signal processing methods including order analysis, synchronous averaging, Vold-Kalman order tracking filtration and measuring the angular vibration **Vehicle Gearbox Noise and Vibration: Measurement, Signal Analysis, Signal Processing and Noise Reduction** Measures is a comprehensive reference for designers of gearing systems and test engineers in the automotive industry and is also a useful source of information for graduate students in automotive and noise engineering.

Planetary Gear Train Microcrack Detection Using Vibration, Grayscale Images and Convolutional Neural Networks Suveen Emmanuel 2020 Planetary Gear Trains (PGT) are widely used in many industrial applications from wind turbines to automobile transmissions due to its high power to weight ratio. Since PGT can be subjected to faults and prone to failure over time, a non-intrusive method of monitoring the condition of PGT is required. Vibration-based machine learning algorithms are mostly used in fault diagnosis and classification in PGT, but due to the epicyclic motion of gears; vibration signals from one gear can get neutralized or amplified by signals from another gear. Identification of smaller cracks in the sun gear can be challenging when using vibration-based fault diagnosis methods due to cancellation effects from the planet pinions. In this paper, the application chosen was based on the epicyclic drivetrain of a Chevy Volt hybrid car. The main research goal of this paper is to solve two research gaps; first is determining if extremely small elliptical cracks the size of 0.02 mm in length can be detected in vibration analysis and second is determining if sun gear faults

neutralized by planetary gear faults can be detected. For that purpose 4 different health conditions of a planetary gear system were simulated using MSC ADAMS software. The conditions are a healthy PGT, PGT with a sun crack, PGT with a planet crack and a PGT with a sun and a planet crack. The joint forces at the exterior ring gear were extracted and a Blackman function was applied to convert to frequency domain values. Each of the frequency domain amplitude values was converted to pixel values in a grayscale image and the generated images were fed into a Convolutional Neural Network to train, validate and test the datasets. The results indicated that the proposed Grayscale – 2D CNN algorithm has an accuracy of 100% for the train and validation sets and 92% accuracy for the test set.

An Investigation of Off-Road Vehicle Power Train Diagnostics Utilizing High Frequency Vibration Analysis

John L. Frarey 1974 The report covers a short three-month program to investigate the feasibility of using high-frequency vibration analysis to diagnose power train condition in off-highway vehicles. The program was conducted on Caterpillar D8H crawler-type tractors. It was found that the use of vibration generated during shift transients to identify spectral regions of interest and to serve as a guide in establishing limits for steady-state vibration analysis appears to be a valid method for diagnosing power train component degradation. Examples of data characteristics considered normal and abnormal for the three major power train components are included in the report. In this respect the program was very fortunate because data from different tractors were recorded and analyzed that varied in age from a new tractor to one that had been used for over 12,000 hours. Train Internal Noise Due to Wheel-Rail Interaction

Wenjun Luo 2019 In order to investigate different potentially effective methods to decrease the noise inside passenger trains, this article employs the acoustic-solid coupling theory and the finite element (FE)-statistical energy analysis (SEA) hybrid method to study the vibration response of the train body under wheel-rail excitation and the internal noise response caused by the vibration of the train body. The contribution of plates to the noise inside the train is also analyzed. The results show that the vibration of the floor has the greatest influence on the noise inside the train. Furthermore, compared with the FE method alone, the FE-SEA hybrid method shortens the computation time and improves the efficiency of the calculation.

Vibration Analysis of a Split Path Gearbox Timothy L. Krantz 1995 Split path gearboxes can be attractive alternatives to the common planetary designs for rotorcraft, but because they have seen little use, they are relatively high risk designs. To help reduce the risk of fielding a rotorcraft with a split path gearbox, the vibration and dynamic characteristics of such a gearbox were studied. A mathematical model was developed by using the Lagrangian method, and it was applied to study the effect of three design variables on the natural frequencies and vibration energy of the gearbox. The first design variable, shaft angle, had little influence on the natural frequencies. The second variable, mesh phasing, had a strong effect on the levels of vibration energy, with phase angles of 0 deg and 180 deg producing low vibration levels. The third design variable, the stiffness of the shafts connecting the spur gears to the helical pinions, strongly influenced the natural frequencies of some of the vibration modes, including two of the dominant modes. We found that, to achieve the lowest level of vibration energy, the natural frequencies of these two dominant

modes should be less than those of the main excitation sources. (AN).

Analysis of Synchronous Belt Vibration in Automotive Valve Train Naohiko Mizuno 1988

Vibration measurement Gh. Buzdugan 1986-08-31 Nowadays, the engineering practice raises far more vibration problems than can be theoretically explained or modelled. Because of this, measurements are used in almost all fields of industry, transportation and civil engineering in studies of mechanical and structural vibration. They are an invaluable tool for designing products and machines with high reliability and low noise level, vehicles and buildings with improved comfort and resistance to dynamic loads, as well as for obtaining increased safety of operation and optimum running parameters. In order to cope with the increasing demand for experimental measurement of vibration characteristics, young engineers and designers need an introductory book with emphasis on "what has to be measured" and "by what means" before learning "how measurements are done". The expertise to perform vibration measurements must be gained in time, with every new investigation and studied problem. A detailed presentation of instrumentation and measuring techniques is beyond the aim of this book. Such information can be found in product data sheets, application manuals and hand books supplied by equipment manufacturers. Only general principles and widely used methods are presented herein, in order to provide the reader with an overview of the instrumentation and techniques encountered in vibration measurement. Traffic Induced Environmental Vibrations and Controls He Xia 2013-01-01

The problem of environmental vibrations induced by moving traffic loads, is today increasingly one of the fundamental problems to be solved in traffic line planning and design, because they not only influence the living and working of human beings, but also make many high-tech projects unable to work normally. Since the effects of various transportation sources are different, and soil properties play a critical role in the propagation of vibrations, the problem of environmental vibrations is very complex. This book contains the research of the authors via fundamental theories, numerical simulations and field experiments. The main contents include the basic theory and analysis approaches in traffic-induced environmental vibrations, prediction and mitigation through ballast mats of rail traffic induced track-ground vibrations, railway traffic induced ground vibration and its prediction approaches, numerical modeling of vibrations induced by rail traffic in tunnels, investigation of train-induced ground vibrations using FEM and field experiments, human induced vibrations of pedestrian bridges and their prevention, prediction of environmental vibration from underground trains, numerical evaluation on train-induced ground vibration around high-speed railway viaducts, vibration isolation by ground barriers, environmental vibration induced by elevated railway traffic, and train induced vibration in elevated railway stations.

Noise and Torsional Vibration Analysis of Hybrid

Vehicles Xiaolin Tang 2022-06-01 Thanks to the potential of reducing fuel consumption and emissions, hybrid electric vehicles (HEVs) have been attracting more and more attention from car manufacturers and researchers. Due to involving two energy sources, i.e., engine and battery, the powertrain in HEVs is a complicated electromechanical coupling system that generates noise and vibration different from that of a traditional vehicle. Accordingly, it is very important to explore the noise and vibration characteristics of HEVs. In this book, a hybrid vehicle with two motors is taken as an example, consisting of a compound planetary gear set

(CPGS) as the power-split device, to analyze the noise and vibration characteristics. It is specifically intended for graduates and anyone with an interest in the electrification of full hybrid vehicles. The book begins with the research background and significance of the HEV. The second chapter presents the structural description and working principal of the target hybrid vehicle. Chapter 3 highlights the noise, vibration, and harshness (NVH) tests and corresponding analysis of the hybrid powertrain. Chapter 4 provides transmission system parameters and meshing stiffness calculation. Chapter 5 discusses the mathematical modeling and analyzes torsional vibration (TV) of HEVs. Finally, modeling of the hybrid powertrain with ADAMS is given in Chapter 6.

Dynamics and Vibration Analyses of Gearbox in Wind

Turbine Qingkai Han 2016-09-27 This book explores the dynamics and vibration properties of gearboxes, with a focus on geared rotor systems. It discusses mechanical theories, finite-element based simulations, experimental measurements and vibration signal processing techniques. It introduces the vibration-resonance calculation method for the geared rotor system in wind turbines and load sharing of the planetary gear train, and offers a method for calculating the vibrations of geared rotor systems under either internal excitations from gear sets or external loads transferred from wind loads. It also defines and elaborates on parameter optimization for planetary gear systems based on the torsional dynamics of wind-turbine geared rotor systems. Moreover, it describes experimental measurements of vibrations on the wind-turbine gearbox performed on the test rig and on site, and analyzes the vibration signals of different testing points, showing them in both time and frequency domains. Lastly, it lists the gear coupling frequencies and fault characteristic frequencies from the vibrations of the gearbox housing. The technologies and results presented are valuable resources for use in dynamic design, vibration prediction and analysis of gearboxes and geared rotor systems in wind turbines as well as many other machines.

Anderson 1997-09-01 The U.S. Navy is currently evaluating an integrated diagnostic system for its rotary wing aircraft. The system is referred to as the Health Usage and Monitoring Systems (HUMS). The program's objective is to develop an automated diagnostic system that can identify mechanical faults within the power train of helicopters using vibration analysis. This thesis uses data provided by the Helicopter Transmission Test Facility at the Naval Air Warfare center, Trenton, New Jersey. The goal of this thesis is to conduct data analysis to identify a fault within the helicopter test transmission using a tree-structured model. Prior to conducting tree analysis, an attempt is made to reduce the amount of data by principal component analysis. All statistical analysis was completed with S-Plus Software (MathSoft Inc., 1995).

A Survey of the Techniques of Random Vibration Analysis, Including an Investigation of the Response of a Linear System to a Train of Impulses Randomly Distributed in Time 1965

Advanced Vibration Analysis S. Graham Kelly 2006-12-19 Delineating a comprehensive theory, Advanced Vibration Analysis provides the bedrock for building a general mathematical framework for the analysis of a model of a physical system undergoing vibration. The book illustrates how the physics of a problem is used to develop a more specific framework for the analysis of that problem. The author elucidates a general theory applicable to both discrete and continuous systems and includes proofs of important results, especially proofs that are themselves instructive for a thorough understanding of the result. The book begins with a discussion of the physics of dynamic systems comprised of particles, rigid bodies, and deformable bodies and the physics and mathematics for the analysis of a system with a single-degree-of-freedom. It develops mathematical models using energy methods and presents the mathematical foundation for the framework. The author illustrates the development and analysis of linear operators used in various problems and the formulation of the differential equations governing the response of a conservative linear system in terms of self-adjoint linear operators, the inertia operator, and the stiffness operator. The author focuses on the free response of linear conservative systems and the free response of non-self-adjoint systems. He explores three method for determining the forced response and

approximate methods of solution for continuous systems. The use of the mathematical foundation and the application of the physics to build a framework for the modeling and development of the response is emphasized throughout the book. The presence of the framework

becomes more important as the complexity of the system increases. The text builds the foundation, formalizes it, and uses it in a consistent fashion including application to contemporary research using linear vibrations.
